Abstract

This is where we will put our abstract.

Plain Language Summary

This is a plain language summary

Source: Article Notebook

1 Introduction

Households juggle how to allocate their budgets: whether to invest in a reliable car, pay for quality childcare, secure housing in a good school district, or set money aside for leisure. These everyday choices shape how families live and move, reflecting the trade-offs they make to balance competing priorities. Transportation often sits at the center of these decisions, not only because it can be a significant expense, but also because choosing to buy and maintain a car versus relying on public transit represents a long-term commitment and a broader lifestyle choice. The way U.S. households choose to spend their money provides evidence of the weight of transportation decisions in a household. For the last 20 years, the average household has allocated between 15 and 20 percent of its budget on transportation expenditures (Bureau of Transportation Statistics, 2024). That is almost double what it was 100 years ago (Johnson et al., 2001). This means that either families are traveling more than they used to or that transportation has become more expensive compared to other household expenditures. Either way, the amount of budget that is put towards a household's travel indicates that transportation is an important part of a family's daily life. The fact that lower income households often have a larger portion of their budget spent on transportation further shows the major role it plays in household decisions and suggests that transportation decisions might have a broader effect on other household expenditures (Molloy et al., 2024).

While transportation is a big portion of the average household's budget, its relative weight compared to housing, childcare, and other spending varies widely across families. Household characteristics like family size, income, car ownership, and location play a role in how much they spend on transportation. For example, people with bigger families or living in single-family homes tend to spend more on transportation (Mattson, 2020). The relationship between household budgeting and mobility is shaped not only by household demographics but also by how families prioritize and weight different needs. On one hand, mobility resources such as car ownership can structure the household budget: households with no or only one vehicle may spend far less on transportation, freeing up income for other essential or discretionary categories. On the other hand, underlying family structures and preferences can drive budget allocation choices that, in turn, shape transportation behavior. Larger families may prioritize childcare or invest in higher-quality housing in areas with better schools, limiting what remains for transportation. Others may emphasize frugality across all categories or deliberately substitute toward lower-cost transit options. Understanding both the direction of influence and the weight assigned to different budget categories is critical for transportation planning and policy, as these dynamics reveal how families navigate competing priorities under varying demographic and mobility contexts.

The purpose of this research is to explore how household budgets are structured around transportation decisions and how this impacts other spending categories. Using the Consumer Expenditure Survey (CEX), we will perform a Latent Class Analysis (LCA) to find groupings based on a household's transportation expenses. These groupings can help us find groups of spenders with similar patterns to help us predict transportation expenses based on the household's characteristics.

Things I haven't included but could maybe include in the future?

- Since 1960, a larger percent of US households have at least one car. It was in the 80s when the percentage of 2-car households surpassed the percentage of 1-car households (Bureau of Transportation Statistics, 2024)

2 Literature Review

Source: Article Notebook

Table 1 summarizes the literature that was reviewed for this study. As seen in the table, there were a total of 35 studies reviewed with 19 studies that use the consumer expenditure survey. The literature relating to this study has been classified into four categories: (1) Household Choices and Activity Patterns, (2) Household Transportation Choices, (3) Household Spending and Budgets, and (4) Household Transportation Budgets. The following sections describe the relevant findings from literature in each of these groups.

Table 1: Summary of the Literature

Study	Uses CEX Data	Category

2.1 Household Activities and Transportation Choices

The literature shows that household dynamics affect the activity patterns of those in the household, and many studies focus on the role children play in these household activities. Some studies aim to find how the presence of children affect the activities of the household (Bernardo et al., 2015), and many studies focus on how children's activities are affected by household demographics (see Sener & Bhat, 2007; Rachel B. Copperman & Bhat, 2007b; Leung et al., 2019; Paleti et al., 2011; Sener et al., 2008). A common finding in these studies is that child activity participation is associated with the environment the child lives in along with household income, parent activities, and other household demographics.

Among the studies on household choices is a group of literature with a specific focus on a household's transportation decisions. A common finding in this group of literature is that household composition plays a role in its transportation choices. Some studies in this group are concerned with the way households use cars or the effect of car ownership on transportation decisions (Amirnazmiafshar & Diana, 2022; Bilgin et al., 2025; Klein, 2024; Lu et al., 2022). These studies show there is a major connection between car ownership and transportation decisions. Other studies are focused on travel choices more generally (Rachel B. Copperman & Bhat, 2007a; Souche, 2010). For an extensive literature review on the transportation choices of households with young children, see the study done by McCarthy et al. (2017).

2.2 Household Spending and Budgets

Another set of studies focuses on household budgets and household spending patterns (Fontes & Fan, 2006; Nayga, 1998; Sabelhaus et al., 2013; Skinner, 1985). Many of the studies reviewed had an emphasis on the budgets related to raising children. Hargunani et al. (2024) analyzed family spending patterns in Mumbai and concluded that many families focus their expenditures on the current and future wellbeing of their children. This is evidenced by money spent on basic necessities and setting aside money for the future.

The United States Department of Agriculture (USDA) has produced reports that use the CEX to specifically analyze the costs of raising a child in the United States. The most recent report (Lino et al., 2017) found the top expenditure for married-couple families with two children to be housing. The rankings of other expenditures were different depending on the age of children, but food, child care/education, and transportation were always the next highest expenditures on children. Similar to the USDA report on the cost of raising children, Osborne et al. (2021) modeled the cost of raising children in Texas by following similar methodologies but using Texas-specific data for housing and childcare costs. They looked not only at married-couple families, but also at single-parent households and duel households where children spend time with both parents in different locations. They found differing expenditures on children among the different family make-ups and among different incomes.

Duncan et al. (2023) performed a study in Canada using the country's Survey of Household Spending (SHS) to analyze family expenditures. They found similar results as previously mentioned studies. Different income groups had different amounts allocated to children, but housing was always the highest expenditure with food, child care/education, and transportation being the next highest expenditures.

Other studies with similar analyses have had similar findings. Hastings (2022) used the CEX to compare expenditures between different racial and ethnic groups. When controlling for both family characteristics and income, he found that there was not a significant difference in total expenditures on children among racial and ethnic groups. This suggests that income and family characteristics play a larger role in family budgeting than race and ethnicity.

2.3 Household Transportation Expenses and Budgets

There have been many studies on family budgets and transportation expenses (Blumenberg, 2003; Choo et al., 2007; Ferdous et al., 2010; Haas et al., 2008; Hong et al., 2005; Morris & Wigan, 1979; Thakuriah (Vonu) & Liao, 2006).

One study focused on transportation budgets was done by Thakuriah & Liao (2005). Using CEX data, they made multiple models to analyze the expenditures related to vehicle ownership of households in the United States. In each model, they used a variety of variables (income, household demographics, spatial factors, economic factors, and family condition factors) to predict the amount of money a household spends on vehicles. Their model results indicate 18 percent of additional household expenditures is a vehicle expense. The results also indicate many factors influence household vehicle expenses. The models showed that homeowners spend more on vehicle expenses. They also showed that vehicle expenses are connected with the sex of the head of household and the number of people in the household.

In a study by Deka (2015), they used two years of the CEX to see the connection between housing expenses and transportation expenses. They created three least squares models: one to describe expenditures in dollar amounts, one to describe expenditures as percentages of income, and one to describe expenditures as shares of total household expenditures. They found a positive association between transportation expenses and housing expenses. Similarly, share of income on transportation was positively affected by share of income on housing, but there was no significant evidence showing the share of income on housing being affected by share of income on transportation. Both housing and transportation expenditures were found to be higher for those living in single-family detached homes and lower for those living in older homes.

Mattson & Peterson (2019) looked at how density, land use, transportation, and household expenditures are related. They developed a regression model using CEX data where transportation expenditures were estimated using type of housing, population, family characteristics, and other factors. Similar to other studies, they found that income is positively associated with transportation expenditures. Their model showed single-family homes to have higher transportation expenditures than other types of dwellings. Using data from the U.S. Census Bureau's Annual Survey of State and Local Government Finances, they also created models to explore how land use might affect municipal spending. In these models, increase in density was associated with a decrease in many per capita operational costs, including fire protection, streets and highways, parks and recreation, and others.

A similar study was published by Mattson (2020) where he modeled transportation expenditures using CEX data. The results showed, like the previous publication, that single-family dwellings spend more on transportation compared to other types. He also found that larger household sizes and newer homes contribute to higher transportation spending.

In their study, Molloy et al. (2024) look at CEX data after proposing a new framework to look at transit users and vehicle users. In past studies, three categories have been used to analyze transportation users: "drivers" are those who own a car, "captive riders" are those who use transit because they ca not afford a car, and "choice riders" are those who can afford a car but do not. Instead of having one grouping for those that own cars, Molloy et al. (2024) propose splitting that category into "captive drivers" and "choice drivers". Captive drivers would be those in the population that are low income but have a car representing people with less transportation freedom. They analyzed the CEX with this new way of classifying transportation users and found that captive drivers carry the most transportation burden. The transportation expenditures of captive drivers average more than 16% of total household expenditures while the transportation expenditures of captive riders was only around 7% of total expenditures.

2.4 The Current Study

Like many of the existing studies described, the current study improves our understanding of household spending patterns and transportation choices. It adds to the literature in three main ways: Dataset, Methodology, and Research Question.

2.4.1 Dataset

Many studies seek to understand household transportation choices with time use diaries or travel surveys. This study, on the other hand, seeks to answer similar questions using expenditure data. Instead of using day to day activities to understand where and how a household is getting around, we use households' weekly expenses to find underlying patterns that explain, and perhaps shape, their travel choices.

Another important thing to note is that all of the reviewed transportation studies using the CEX were using data from before 2020. Since much has changed since the COVID19 pandemic, the 2024 data used in the current study will provide a more timely analysis.

2.4.2 Methodology

The latent class analysis for the current study looks at unique exogenous and outcome variables. To perform the analysis, we created categories to reflect the type of expenditures made. We used these unique categories in the analysis. The exogenous and outcome variables we used in the analysis are listed below.

- List of variables used in analysis

2.4.3 Research Question

The purpose of the current study is to see how household budgets are structured around transportation decisions. We are going about it with the perspective that transportation expenditures help define a household. Looking at the data in this way will help us find trends that were perhaps missed in other studies on transportation decisions.

Table 2: Diary Survey files available in the Public Use Microdata (PUMD)

File Name	Description
FMLD	Characteristics and summary expenditures for each household
MEMD	Characteristics for members of each household
EXPD	Detailed expenditure data
DTBD	Detailed income
DTID	Income imputation iterations

3 Data

Data for the following analysis were obtained from the 2024 Consumer Expenditure Survey (CEX) Public Use Microdata (PUMD). The CEX is administered continuously by the Bureau of Labor Statistics (BLS). The data are organized by quarter and published each year. The CEX consists of two surveys: the Interview Survey, and the Diary Survey. Each survey has it's own unique sample, so the households in one will not appear in the other. The Interview Survey tracks a household's major and recurring expenditures by reviewing their expenses from the past three months, and the Diary Survey captures more routine household spending by recording in detail a households expenditure across a two-week span.

Because we were interested in the day-to-day expenditures of households, this study uses data from the Diary Survey of the CEX. To gather this data, BLS personnel contact a sample of US households, record household demographic data, and explain how to fill out the weekly expenditure diary. After two consecutive weeks of reporting expenditures, the household is removed from the sample and replaced by a new household. The combination of household demographics and detailed expenditures available in the Diary Survey makes this data set ideal for the current study.

Table 2 shows the files in the PUMD that pertain to the Diary Survey. For this study, we specifically looked at the FMLD and the EXPD files from 2024 to get household[1] characteristics along with their detailed spending tables. In the 2024 data, there were a total of 6,334 households surveyed. To capture the most expenditures and keep consistency, we only kept households that had participated in the study for two consecutive weeks during the study period. We also excluded any households who had no recorded expenditures during the two survey weeks. After filtering out the 161 households with only one week of data and the 169 households with no expenditures, we were left with 6,004 households used in the analysis.

Source: Article Notebook

Source: Article Notebook

In the expenditures data, there were 410 unique types of expenditures recorded with each expenditure designated by a Universal Classification Code (UCC). We organized this into 7 categories as shown in Table 3 (for a more detailed breakdown of the expenditure categories, see Appendix A). Since this study focuses on transportation expenditures, we further split the transportation category into smaller categories based on mode. The specific UCC codes for each item in the transportation categories are listed in Table 4.

[1] Note that "household" in this paper is synonymous with what the CEX often denotes as "Consumer Unit" (CU)

Table 3: Details of spending categories

Category	Types of Expenses
Food	Purchases related to food and alcohol.
House Related	Rent, utilities, maintnance, furniture, etc.
Leisure	At-home entertainment, sports and recreation equipment, etc.
Mandatory	Clothing, hygiene, medical, etc.
Other	Gifts, retirement plans, legal fees, tobaccos products, etc.
School	Tuition, school supplies, etc.
Transportation	Purchases related to transportation

Source: Article Notebook

Source: Article Notebook

The average spending in each of the major categories mentioned above is shown in Table 5. As seen in the table, there were four categories in which more than 75% of the sample had expenditures: food, house, mandatory, and transportation. The portion of the sample with food-related expenditures was just under 100 percent, and those with house-related expenditures was over 80 percent. This shows that practically no household went two weeks without purchasing food, and only a small portion of the households went two weeks without having a house-related expense. When including all the households in the sample, the average spending on transportation is approximately $260, and that average increases to approximately $325 when looking at only the households who had transportation expenditures.

The average spending in each of the specific transportation categories is found in Table 6. Car fuel and car maintenance were the the expense categories that included the most households. The categories with the highest averages were car purchases, car payments, and ship travel, but these had relatively low numbers of households spending any money in the categories.

Source: Category Spending Tables

Source: Category Spending Tables

Most of the census data was found using the Census Bereau Tables. For city population, I used the census city and town population totals data.

Highlights of Table **??**

- CES had more people in the <$50K and less people in the >$200k. This is most likely because it is harder to get people in the higher income bracket to participate in the survey.
- CES had less people in the younger age group and more in the older age group. This is most likely because we are comparing reference person age to just age in general. It makes sense that there are more 54+ people as reference person since the odds of older people owning a house is larger.
- CES had more people. with bachelors degree or higher. I don't know why, but could be connected to the city population. Maybe people with degrees are more likely to live in large cities over a million people.
- The unmarried group is slightly lower in the CES survey. I'm not sure why, but I'm not sure it even needs to be talked about.

Table 4: Unique Expenditures in Each Transportaiton Category

	UCC Code	Code Description
Car Purchase	520516	Auto/truck rental
	530903	Car/van pool & non-motorized transp
	450110	New cars
	450210	New trucks
	460110	Used cars

Train Travel	530311	Intracity mass transit fares
	530510	Intercity train fares
Taxi or Limo Travel	530412	Taxi fares and limousine services
Bike or Scooter or other Single Rider Travel	600310	Bicycles
	600315	Scooters, and other single rider transp
	600311	Bike and E-scooter sharing or rental (
Air Travel	520901	Docking and landing fees
	530110	Airline fares
Ship Travel	530901	Ship fares

Table 5: Average Spending per Household in Each Category

Table 6: Average Transportation Spending per Household in Each Category

Table 7: Class Distribution of Model

Table 8: Regression Results of Model

- The biggest discrepancy is the city population. I think it says somewhere that the ces surveys are over-representative of large cities??

Then there might still be some tables Katie wanted me to make. I will review those.

3. Table with the buckets of transportation spending category splits.
4. Same averages, but split them up by different household structures

- Refer to R code on how to do this efficiently.
- This is where we can start to tell the story that perhaps different household structures are spending their money in different transportation spending categories.

4 Results

The analysis resulted in three latent classes which we named based on the household distribution of each class. The latent classes are described as follows.

4.1 Class 1: Car Spenders High (CH)

This class mostly contains households that spend higher amounts of money on car-related travel. As shown in Table 7, the *CH* class has a much larger percent of households that spent over $100 on both fuel and maintenance during the survey period. In those same categories, it had the smallest percent of households spending nothing in those categories. In terms of other modes of transportation, this class hardly had any households with expenses in the other transportation categories.

4.2 Class 2: Multimodal Spenders (MM)

Unlike the *CH* category, the *MM* class contains a higher percentage of households that had spending in the transportation categories not involved with cars. For example, while less than 2% of households in the *CH* class spent any money on train travel, more than 50% of households in this class spend money on train travel with about 30% of households spending over $20 on train travel.

4.3 Class 3: Car Spenders Low (CL)

Similar to the *CH* class, the *CL* class had most expenditures in the car categories. However, there was a smaller percent of households with expenses in the higher ranges. For example, the *CH* class had over 45% households that spent over $100 on fuel while the *CL* class had less than 15% exceeding $100 in fuel. Like the *CH*, the *CL* class had very low percentages of households that spent money on modes besides cars. In fact, there were no households in this class that spent money on trains or buses.

Source: LCA Tables

Table 8 shows the regression results of the latent class model. As seen in the table, most of the model coefficients are statistically significant. The following sections discuss the findings in more detail.

Source: LCA Tables

4.4 Household Make-up

Compared to single people with no children, both households with children and households with a married couple are more likely to be in the CH class than in the MM class. This makes sense to see that households with more people are more likely to have their transportation expenses oriented around cars because heavier travel demands and the balance of multiple schedules increases the convenience of a car. This also aligns with the study by Thakuriah & Liao (2005) which found vehicle expenses to be connected to the number of people in the household. Comparing the MM class to the CH class, the coefficient for "married without children" households has the smallest absolute value, this shows that having children in the household has a stronger effect on being in the CH class than having a married couple in the household does. This "married without children" variable is also the only one with a statistically significant coefficient when comparing the CL class to the CH class. This means that "married without children" households are more likely to be in the CH class than the CL class compared to "single" households. This also makes sense because married couples will most likely have more trips than a single person, and this will equate to more transportation spending.

4.5 Location

Compared to other areas of the country, households in the northeast are more likely to be in the MM class than in in the CH class. This also makes sense because the northeast is relatively dense and has some of the longest history of transit use. Additionally, household in cities of more than one million people are less likely to be in the CH class compared to the other classes. This makes sense for similar reason as the region findings.

- (There is probably a study on how the more populous areas have less car use.)

The findings from the coefficients for both the region and the city size support findings in other transportation studies. Deka (2015) found transportation expenditures to be higher for those living in single-family, detached homes and lower for those living in older homes. Mattson & Peterson (2019) and Mattson (2020) also found a positive correlation between transportation expenses and living in a single family home. The density and history of the northeast region of the united states, and of most large cities, makes it more likely to have old homes and higher concentrations of multifamily homes. These places will be more likely to spend less on transportation and use modes other than cars.

4.6 Other Household Demographics

Compared to people that are 55 years old or older, households with a reference person younger than 55 are more likely to be in the MM class as opposed to the CH class. Additionally, households with a reference person younger than 55 are more likely to be in the CH class as apposed to the CL class. It makes sense that people older than 55 are more likely to use cars, but, compared to everyone who spends money on cars, they are more likely to be small spenders because they don't have as many trips.

- (There is probably a study on how younger adults are more likely to take transit or active transportation)

Compared to those making more than \$50,000 a year, those making less than \$50,000 a year are less likely to be in CH as apposed to both MM and CL. This makes sense and aligns with previous studies. Household with less income will most likely spend less on transportation (Molloy et al., 2024; Sener et al., 2008).

Compared with those who don't have a college degree, those with a degree are more likely to be in the MM class as opposed to the CH class. Compared with those who don't have a college education, those with bachelors degree are more likely to be in

Table 9: The table that Katie gave me the code to make.

the CH class as opposed to the CL class while those with a doctorate degree are more likely to be in the CL compared to the CH class. This could be because people with doctorates have more opportunities to work from home or more flexibility to live close to their work.

4.7 Household Expenditures

Compared to those who spend nothing in mandatory spending, those who have mandatory expenses, are more likely to be in the CH class as opposed to the MM class. Compared to those who spend nothing in mandatory spending, those who have mandatory expenses, are more likely to be in the CH class as opposed to the CL class. The different coefficient values show that people spending over $500 on mandatory spending are more likely to be in CH class compared to the households spending less on mandatory things.

Compared with households who have no house-related expenses, households with house related expenses are more likely to be in the CH class. It also looks like, in both comparisons, that the higher people are paying on house-related expenses, the more likely they are to be in the CH class compared to those without house-related expenses.

Compared to those households who spend less than $100 on leisure, households who spend more than $100 are more likely to be in the CH class. It makes sense that spending on Leisure activities would be positively correlated with transportation spending since the more spend on leisure could very likely indicate more trips made.

The coefficients related to household spending tend to increase in absolute value as the spending ranges increase. It is reasonable to see the probability of being in the high spending transportation class increase as other household expenses increase. More household expenses often mean more trips are being made.

4.8 Some More Results

I think Table 9 is showing what percent of households fall into each category in each class. But I just put this in here to look at it. It won't be in the final paper.

6 Appendix A: Spending Category Breakdown

Source: Article Notebook

Table 10: Unique expenditures and UCC codes for each expenditure category

	UCC Code	Code Description
Transportation	520901	Docking and landing fees
	530110	Airline fares
	600310	Bicycles
	600315	Scooters, and other single rider transportation (new UCC Q20191)
	600311	Bike and E-scooter sharing or rental (new UCC Q20192)
	530902	School bus
	530210	Intercity bus fares
	470111	Gasoline
	470112	Diesel fuel
	470114	Gasohol
	480100	Vehicle maintainance and repair, excluding tires
	480110	Tires - purchased, replaced, installed
	490000	Misc. auto repair, servicing
	490315	Brake adjustment (old)
	620114	Automobile service clubs and GPS services
	490100	Vehicle maintenance/repair excluding tire purchase (new UCC Q2
	500110	Vehicle insurance
	510115	Vehicle registration including property tax
	520310	Drivers' license
	520410	Vehicle inspection
	520516	Auto/truck rental
	520531	Parking fees in home city, excluding residence
	520541	Tolls or electronic toll passes
	520550	Towing charges
	530903	Car/van pool & non-motorized transportation
	450350	Car/truck lease payments
	450110	New cars
	450210	New trucks
	460110	Used cars
	460901	Used trucks
	460902	Used motorcycles
	520902	Motorcycle rental
	530901	Ship fares
	530412	Taxi fares and limousine services
	530311	Intracity mass transit fares
	530510	Intercity train fares
Food	200310	Includes all wine and wine based low alcohol refreshers purchased
	790420	Alcoholic beverages at restaurants or taverns
	200119	Beer, ale, and other malt beverage (new UCC Q20231)
	200219	Distilled spirits (new UCC Q20231)
	190400	Food and nonalcoholic beverages at fast food
	190500	Food and nonalcoholic beverages at full service restaurants
	190600	Food and nonalcoholic beverages at vending machines and mobile
	190700	Food and nonalcoholic beverages at employer
	190902	Catered Events, and Other Food Away From Home includes catere
	010119	Flour and flour mixes, includes all types and varieties of flour. Exa
	010210	Ready-to-eat and cooked cereals
	010310	Rice
	010320	Pasta, cornmeal and other cereal products
	020310	Biscuits and rolls
	020410	Cakes and cupcakes
